

4. AR Vision

4.1. Overview

Augmented Reality, referred to as "AR", is a technology that cleverly integrates virtual information with the real world. It widely uses multimedia, three-dimensional modeling, real-time tracking and registration, intelligent interaction, sensing and other technical means to simulate computer-generated text, images, three-dimensional models, music, video and other virtual information and apply them to the real world. The two types of information complement each other, thereby achieving "enhancement" of the real world.

The AR system has three outstanding characteristics: ① Information integration of the real world and the virtual world; ② Real-time interactivity; ③ Adding and positioning virtual objects in three-dimensional space.

Augmented reality technology includes new technologies and new means such as multimedia, three-dimensional modeling, real-time video display and control, multi-sensor fusion, real-time tracking and registration, and scene fusion.

4.2. Usage

When using AR cases, the camera's internal parameters must be used, otherwise it cannot be run (the factory image has completed the camera internal parameter calibration). The internal parameter file is in the same directory as the code.

4.2.1, Camera internal parameter calibration

Start the monocular camera

```
ros2 launch usb_cam camera.launch.py
```

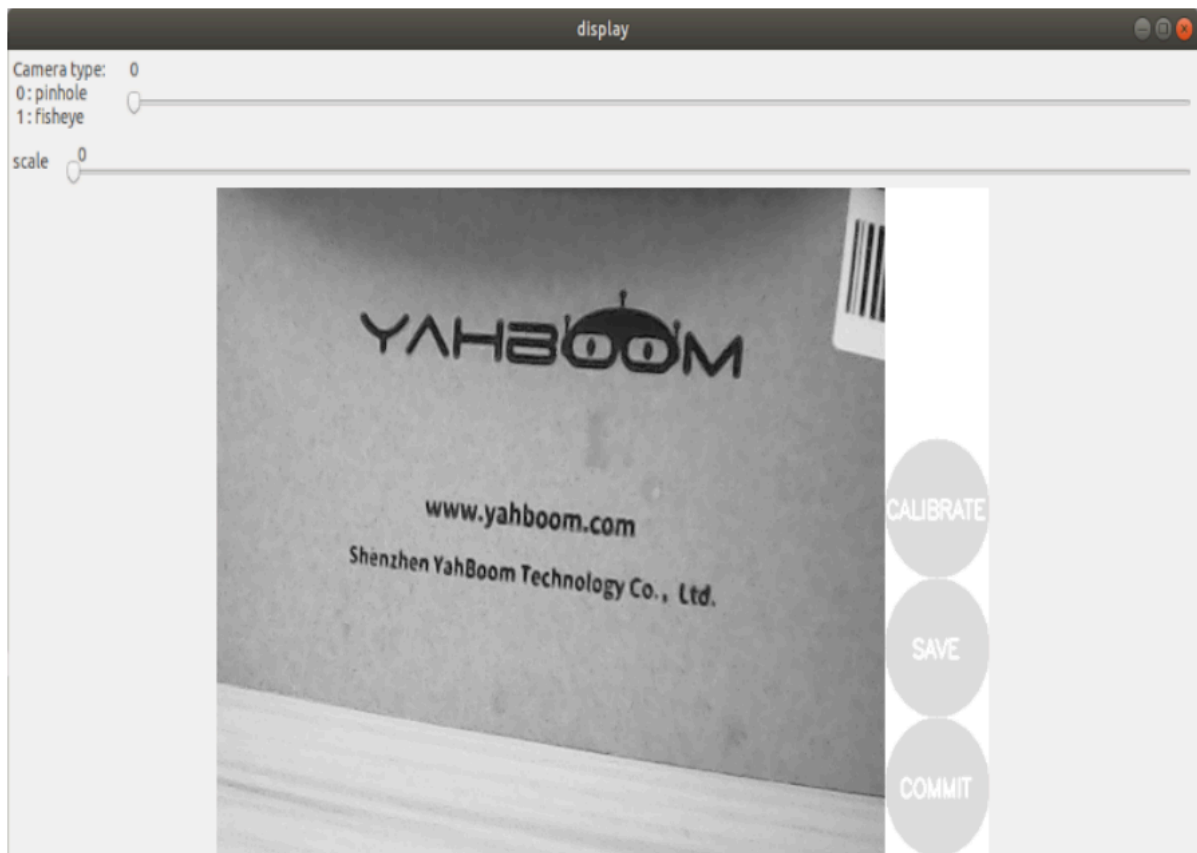

Start the calibration node

```
ros2 run camera_calibration cameracalibrator --size 9x6 --square 0.02 --ros-args  
--remap /image:=/usb_cam/image_raw
```

size: The number of internal corner points of the calibration chessboard, for example, 9X6, the corner points have six rows and nine columns.

square: The side length of the chessboard, in meters.

image: Image topic released by the camera

Calibration interface

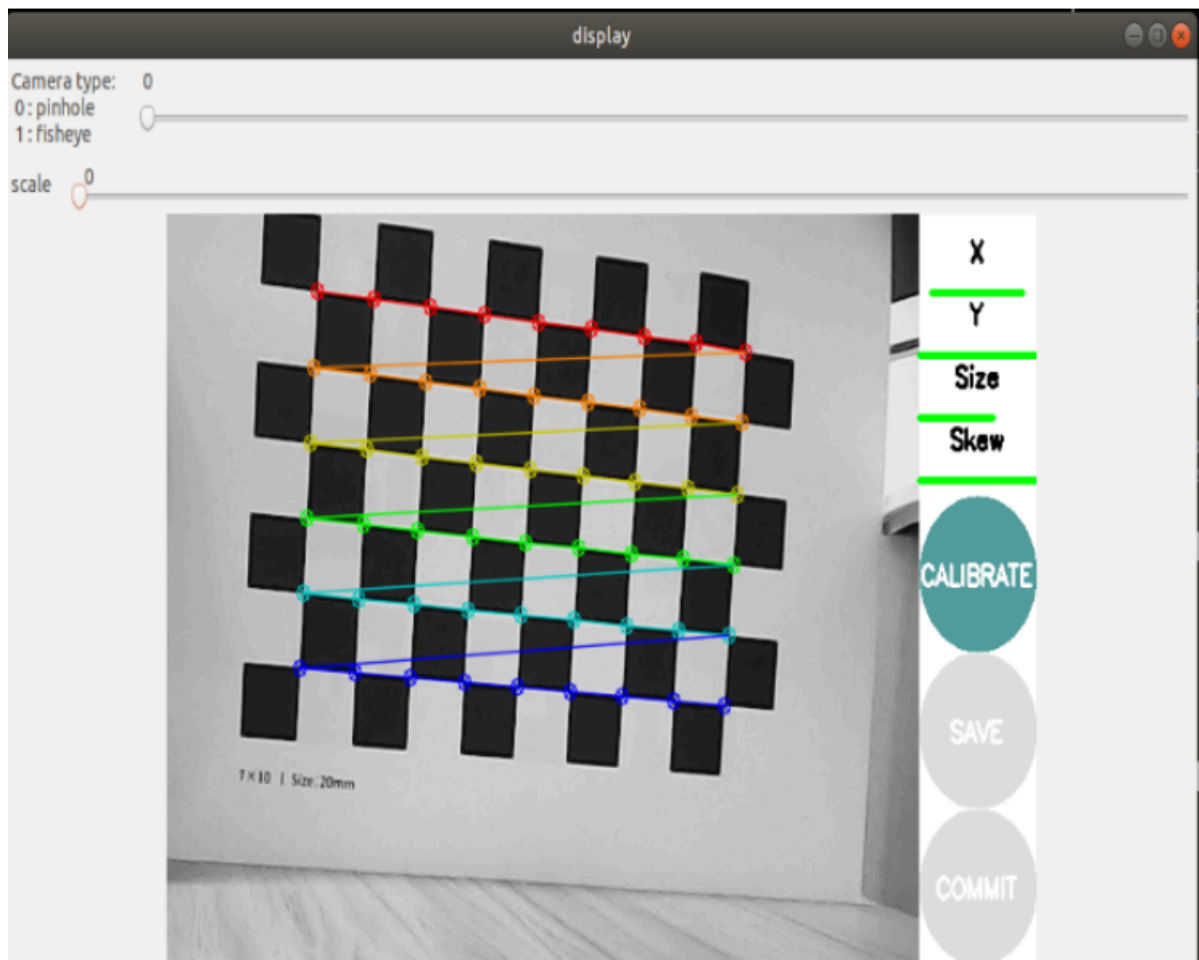

X: Left and right movement of the chessboard in the camera's field of view

Y: Up and down movement of the chessboard in the camera's field of view

Size: Front and back movement of the chessboard in the camera's field of view

Skew: Tilt and rotation of the chessboard in the camera's field of view

After successful startup, place the chessboard in the center of the screen and change different positions. The system will recognize it autonomously. The best situation is that the lines under [X], [Y], [Size], and [Skew] change from red to yellow and then to green as data is collected, and fill as much as possible.

- Click [CALIBRATE] to calculate the camera internal parameters. The more pictures there are, the longer it will take. Just wait. (Sixty or seventy pictures are enough. Too many will cause the system to get stuck easily).
- Click [SAVE] to save the calibration results to [/tmp/calibrationdata.tar.gz] of the current running terminal.

After the calibration is completed, you can move out the [/tmp/calibrationdata.tar.gz] file to check the contents.

```
sudo mv /tmp/calibrationdata.tar.gz ~
```

After decompression, there are the pictures just calibrated, an ost.txt file and an ost.yaml file. ost.yaml is the internal parameters of the calibrated camera. Copy the contents of the internal reference here and overwrite it to camera.yaml under ~/jetcobot_ws/src/jetcobot_visual/config.

Then modify the file to add 5 places,

```
sudo vim /home/jetson/jetcobot_ws/src/jetcobot_visual/config/camera.yaml
```

```

YAML:1.0
---
image_width: 640
image_height: 480
camera_name: camera
camera_matrix: !!opencv-matrix
  rows: 3
  cols: 3
  dt: d
  data: [ 949.60962,  0.    , 242.57827,
          0.    , 948.21184, 318.8214 ,
          0.    ,  0.    ,  1.    ]
distortion_model: plumb_bob
distortion_coefficients: !!opencv-matrix
  rows: 1
  cols: 5
  dt: d
  data: [-0.412660, 0.167212, 0.001182, 0.011953, 0.000000]
rectification_matrix:
  rows: 3

```

Note: The factory image has been calibrated with parameters and can be used directly by starting the program. If the camera screen is started, please close the camera process first and then start the program.

4.2.2, Program Startup

Terminal input,

```
ros2 run jetcobot_visual simple_ar
```

After the program starts, place the chessboard in front of the camera. Note that you need to see the entire chessboard, otherwise the program will exit. After the entire chessboard is recognized, the following 12 effects will be displayed,

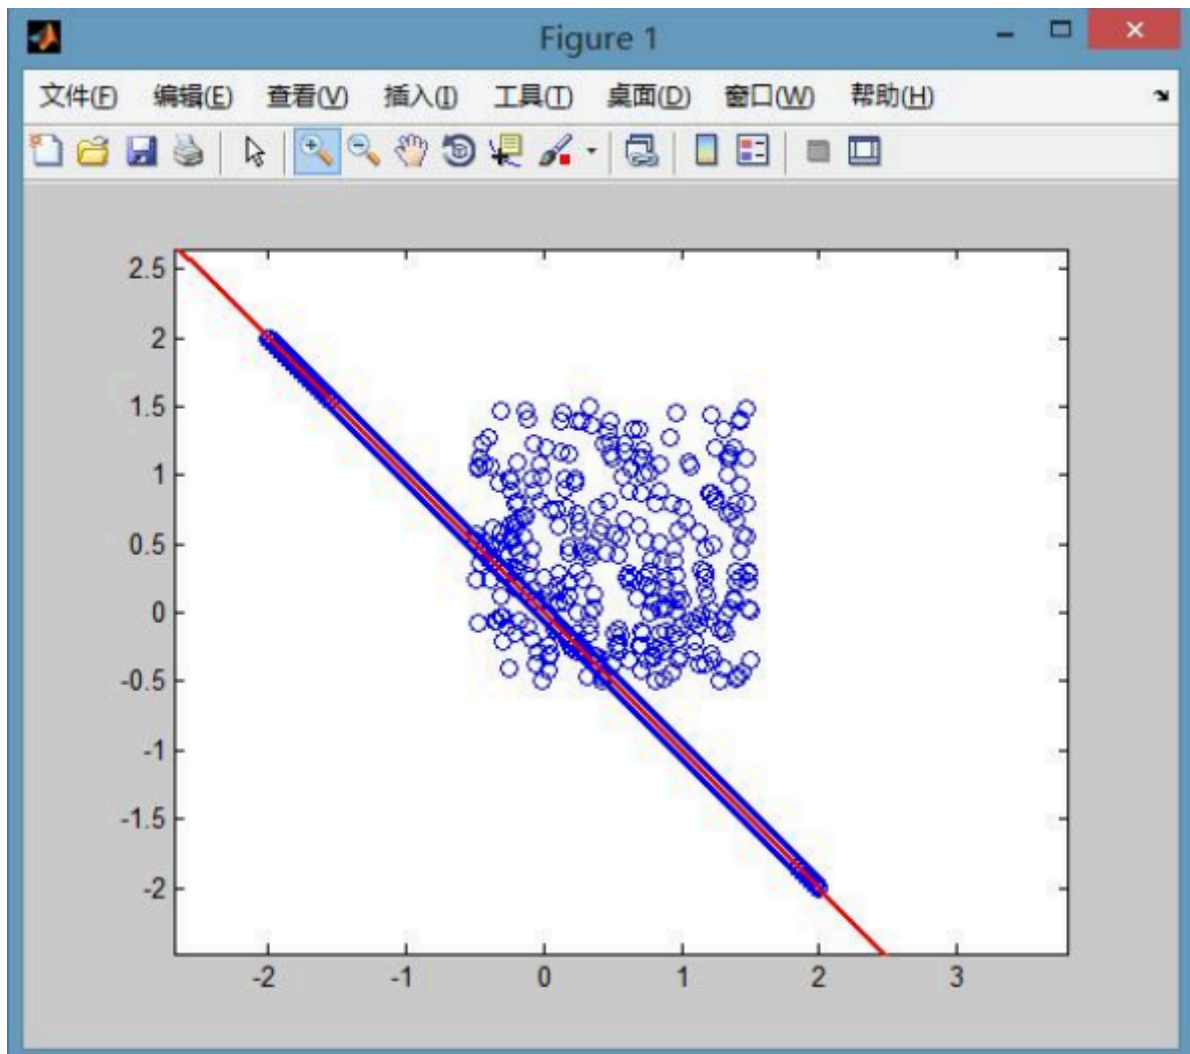

```
["Triangle", "Rectangle", "Parallelogram", "WindMill", "TableTennisTable",  
"Ball", "Arrow", "Knife", "Desk", "Bench", "Stickman", "ParallelBars"]
```

Click the image and press F to switch the displayed effect.

4.3.1, RANSAC scheme

- Algorithm principle: Use the RANSAC scheme to find the object posture from 3D-2D point correspondence

The Ransac algorithm (random sampling consensus) was originally a classic algorithm for data processing. Its function is to extract specific components in an object under a lot of noise. The following figure is an illustration of the effect of the Ransac algorithm. Some points in the figure clearly satisfy a certain straight line, and another group of points is pure noise. The purpose is to find the equation of the line under a lot of noise. At this time, the amount of noise data is 3 times that of the line.

If the least squares method is used, such an effect cannot be obtained. The straight line will be slightly above the straight line in the figure.

- The basic assumptions of RANSAC are:

- The data consists of "inliers", for example: the distribution of the data can be explained by some model parameters;
- "Outliers" are data that cannot fit the model;
- Data other than this is noise.
- Outliers are caused by: extreme values of noise; incorrect measurement methods; incorrect assumptions about the data. RANSAC also makes the following assumptions: given a set of (usually small) inliers, there is a process that can estimate the model parameters; and the model can explain or apply to the inliers.

4.3.2, Source code

Source code location: ~/jetcobot_ws/src/jetcobot_visual/jetcobot_visual/simple_ar.py

```
#!/usr/bin/env python
# -*- coding: utf-8 -*-
